PYTHON PROGRAMMING | EXERCISE 01

Regular Expressions in Python

Pattern matching and search

This exercise shows how Python's re module distinguishes a match at the start of a string from a search anywhere in the string.

Question

Write a Python program that demonstrates how to use regular expressions to match and search for patterns in text.

Code

```
import re

text = "Order status: ORD-1042 is shipped. Related order: ORD-2025."

start_match = re.match(r"Order", text)
order_search = re.search(r"ORD-\d{4}", text)

print("Text:", text)
print("re.match(r'Order', text):", start_match.group(0) if start_match else None)
print("re.search(r'ORD-\d{4}', text):", order_search.group(0) if order_search else None)
```

Output

```
Text: Order status: ORD-1042 is shipped. Related order: ORD-2025.
re.match(r'Order', text): Order
re.search(r'ORD-\d{4}', text): ORD-1042
```
